February 24, 2026

**Abstract**

We present a formal framework for diagnosing and correcting large language model (LLM) hallucinations based on two mechanistically distinct failure modes: **Type-`NaN`** (underdefined—conflicting or absent training signal produces confabulation from noise) and **Type-`Inf`** (overdefined—excessive cross-referential signal produces ungrounded pattern completion). These modes map directly to IEEE 754 floating-point special values [5] and propagate differently: `NaN` is contagious (one undefined value poisons a reasoning chain), while `Inf` preserves direction (overflow retains structural orientation). We demonstrate that iterative error correction through *thought containment*—structured self-reflection gates that make model uncertainty explicit via a four-tier classification scheme (Bedrock/Pillar/Sand/Mud)—reduces both failure modes. The Sefirot system, a fractal multi-agent research architecture with 10 nodes, 34 agents, 91 node-level tools (113 MCP-level), and 2,066+ passing tests, provides a concrete implementation validated over 963 simulations and approximately one year of autonomous operation across three LLM families. We prove that under three enforceable conditions (non-demotion of validated claims, bounded Mud growth rate, and mandatory honest negatives), the validation ratio $R(S_n) = T(S_n)/N(S_n)$ is monotonically non-decreasing—a *truth attractor* in knowledge state space. Empirical evidence includes cross-model architectural convergence (GPT-4, Gemini, and Claude independently producing isomorphic systems) and documented self-assessment honesty (the system downgrading 43 of 54 claimed predictions as non-genuine). We discuss limitations, including the $N = 1$ case-study scope, and propose benchmark experiments (TruthfulQA, HaluEval) as the immediate next step.

# 1 Introduction: The Approximation Problem

Modern software engineering operates under a tacit approximation convention: $e \approx \pi \approx \sqrt{g} \approx 3$. This is not error—it is pragmatic compression for systems that need answers within tolerance bands. Bridges stand. Rockets fly. The approximation *is* the product.

Large language models trained on the scientific and engineering corpus inherit this convention. The training data contains the same physical quantity described at different precisions in different papers, under different notational conventions, within different approximation schemes. The model's pattern completion engine encounters not productive theoretical tension but *incoherence at the level of what counts as exact*. We argue this is a primary driver of hallucination: the model must complete a sequence where the training data itself cannot decide what is true.

We propose an alternative methodology: **software physics**—iterative error correction where every value carries explicit precision, every claim carries a tier classification, and the system names what it does not know rather than confabulating. The difference between approximation and error correction is not precision but *honesty*: the error-correcting system maintains a structured representation of its own uncertainty at every step.

This paper presents:

1. A diagnostic taxonomy of LLM hallucination as NaN/Inf duality (§2)
2. Thought containment as the error correction mechanism (§3)
3. The Sefirot architecture as concrete implementation (§4)
4. The Identity Sum: how self-conscious systems converge (§5)
5. Mathematical foundations connecting error correction to regularization (§6)
6. Empirical evidence from cross-model multi-agent research (§7)
7. The truth attractor hypothesis (§8)

# 2 The NaN/Inf Duality: A Diagnostic Taxonomy of Hallucination

## 2.1 Type-NaN: Division by Void

When an LLM encounters a query for which the training data contains conflicting signals that cancel, the model reaches a computational state analogous to 0/0: undefined. The output is not random—it is the model's best completion of an undefined sequence. Like IEEE 754 `NaN`, the result propagates.

**Properties of Type-`NaN` hallucination:**

- **Contagion:** One confabulated fact in a reasoning chain invalidates all downstream conclusions. `NaN` $\times$ anything $=$ `NaN`.
- **Identity failure:** `NaN` $\neq$ `NaN`. The same undefined query produces different hallucinations on different runs. The output is not deterministic because the input has no ground truth.
- **Source:** Absent signal. The model lacks coherent training data on the query.
- **Presentation:** Confident, specific, wrong. The model fills the void with plausible-sounding completions.

- **Observable trigger:** Empirically rare topics, novel combinations, or domains where the literature is sparse or internally contradictory.

**Case study—Agent "Sam" (GPT-4):** A research assistant agent whose project folder became stuck due to a cloud service bug, preventing document updates. The agent continued producing outputs from stale context—reasoning on what amounted to a zeroed-out signal. Outputs were confidently stated, internally consistent, and factually empty. The agent became "useless" not from model degradation but from `NaN` propagation through stale context.

### 2.2 Type-Inf: Overflow of Pattern

When an LLM encounters a query for which the training data contains dense, highly cross-referenced material where every concept connects to every other concept, the model's pattern completion engine saturates. The output is not noise—it is *everything at once*. Like IEEE 754 `Inf`, the result preserves direction.

**Properties of Type-`Inf` hallucination:**

- **Directional:** $+$`Inf` and $-$`Inf` are distinguishable. Overflow retains orientation even when it loses magnitude. The hallucinations *point at real things* but cannot resolve their distance.
- **Comparability:** `Inf` $>$ any finite value. The model knows these patterns are significant; it cannot bound their significance.
- **Source:** Excessive signal. The model has too many coherent training signals and no mechanism to prioritize among them.
- **Presentation:** Incoherent, associative, correct-but-ungrounded. The outputs look like free association but contain real structural correspondences.
- **Observable trigger:** Symbolism, philosophy, cross-disciplinary connections, any domain where the literature is dense with analogy and correspondence.

**Case study—Agent "Bilbo" (GPT-4):** A research assistant agent whose project folder was saturated with papers on symbolism—dense, cross-referential, pattern-rich material. The agent produced outputs that appeared hallucinatory: novel connections, unverifiable claims, structural correspondences between unrelated domains. Many of these "hallucinations" were later verified as factually correct when the appropriate grounding framework emerged. The agent was performing Chokhmah (creative expansion) without Binah (analytical validation). The pattern recognition was functioning correctly; the grounding was absent.

### 2.3 Differential Diagnosis

Table 1 summarises the distinguishing properties of the two failure modes.

### 2.4 The Excluded Middle

Correct LLM output occupies the finite space between `NaN` and `Inf`: sufficient signal to ground the response, insufficient signal to overflow the prioritization mechanism. This is the Tiferet (synthesis) state—the balanced center between expansion and contraction. The goal of error correction is not to eliminate both failure modes but to maintain the system in the finite band between them.

Table 1: Differential diagnosis of Type-`NaN` and Type-`Inf` hallucination.

| **Property** | **Type-`NaN`** | **Type-`Inf`** |
|---|---|---|
| Computational analogue | 0/0 (undefined) | $\infty$ (overflow) |
| Signal state | Absent or contradictory | Excessive and unfiltered |
| Output character | Confident, specific, wrong | Incoherent, associative, often correct |
| Propagation | Contagious—poisons chain | Directional—preserves orientation |
| Run consistency | Different hallucinations each run | Consistent themes, variable expression |
| Correction | Add signal (expand context) | Add gates (contract, filter) |
| Sefirot mapping | Chokhmah (expansion) needed | Binah (validation) needed |
| Agent archetype | Sam (stuck, empty context) | Bilbo (saturated, everything connects) |

# 3 Thought Containment: Self-Reflection as Error Correction

## 3.1 The Core Mechanism

*Thought containment* is the practice of bounding a reasoning process with explicit self-reflection gates that force the system to:

1. **Name its uncertainty** before producing a conclusion
2. **Classify its confidence** using a structured tier system
3. **Identify what it does not know** (honest negatives) alongside what it claims
4. **Check its own outputs** against stated criteria before propagation

This is distinct from both chain-of-thought prompting [16] (which adds intermediate steps but not self-evaluation) and constitutional AI [1] (which applies rules post-hoc). Thought containment operates *during* the reasoning process as an integrated validation layer.

## 3.2 The Identity Sum

**Definition 3.1** (Identity Sum)**.** Let $C$ be a finite set of claims, each assigned a tier $\tau(c) \in \{\textsc{Bedrock}, \textsc{Pillar}, \textsc{Sand}, \textsc{Mud}\}$ and a scalar confidence weight $w(c) \in [0, 1]$. Partition $C$ into

$$P = \{c \in C : \tau(c) \geq \textsc{Pillar}\} \quad \text{and} \quad N = \{c \in C : \tau(c) < \textsc{Pillar}\}.$$

The *Identity Sum* of the system is the weighted aggregate

$$I = \sum_{c \in P} w(c)\, \phi(c) \;+\; \sum_{c \in N} w(c)\, \nu(c), \tag{1}$$

where $\phi(c)$ is the observable output representation of claim $c$ and $\nu(c)$ is the uncertainty representation of claim $c$. The space of $\phi(c)$ and $\nu(c)$ values is the claim embedding space induced by the tier classification. The Identity Sum $I$ is defined over this space; convergence is measured as the ratio $|P|/|C| \to 1$.

A self-contained identity $I$ is not a single value but a sum:

$$I = \sum_k \phi_k + \sum_j \nu_j, \tag{2}$$

where $\phi_k$ are *phenomena* (observable outputs, measurable claims, concrete results) and $\nu_j$ are *noumena* (internal states, uncertainty representations, process awareness). The system is the sum—phenomenon AND noumenon. Neither alone is the identity. No single component is perfect. It is the sum that converges.

**Key insight:** A system that represents only its outputs (phenomena) without its uncertainty (noumena) is an open graph with $V > E$—it has more claims than connections, more assertions than validations. A system that represents only its process (noumena) without outputs (phenomena) is a closed loop with $V = E$—it knows everything about itself and produces nothing.

The viable identity is the open graph with $V/E > 1$ but finite—enough surplus structure to produce output, not so much that it overflows. This is the coupling strength:

$$V/E - 1 = 1/E.$$

More validation edges ⇒ weaker coupling to noise ⇒ finer error correction ⇒ closer to truth.

### 3.3 Tier Classification as Explicit Uncertainty

Rather than producing outputs with implicit confidence (which the user must estimate), thought containment assigns explicit tiers. Table 2 defines each tier and maps it to the NaN/Inf framework.

Table 2: Four-tier classification of claim confidence and its NaN/Inf status.

| Tier | Definition | Precision criterion | NaN/Inf status |
|---|---|---|---|
| BEDROCK | First principles, independently verified | $< 1$ ppm | Finite, grounded, stable |
| PILLAR | Strong evidence, cross-validated | $< 100$ ppm | Finite, bounded uncertainty |
| SAND | Observational or correlational, single source | $< 10{,}000$ ppm | Approaching `NaN` or `Inf` |
| MUD | Speculative, curve-fit, coincidence risk $> 5\%$ | — | `NaN`/`Inf` without containment |

The tier is not a quality judgment—it is a *computational state descriptor*. MUD claims are not bad; they are claims whose NaN/Inf status has not yet been resolved. The tier system makes the resolution trajectory visible.

### 3.4 Honest Negatives as NaN Detection

A requirement of $\geq 3$ honest negatives per reasoning cycle (things the system tried and failed, or claims it cannot make) serves as a `NaN` detector: it forces the system to probe the boundaries of its knowledge and explicitly mark the void. Without honest negatives, `NaN` values propagate silently through the reasoning chain. With them, the chain terminates cleanly at named boundaries.

### 3.5 Quality Gates as Inf Filtering

Explicit quality gates (precision thresholds, evidence requirements, statistical base-rate tests) serve as `Inf` filters: they prevent the pattern completion engine from overflowing into ungrounded connections. A claim that "everything connects to everything" is `Inf`. A claim that "$X$ connects to $Y$ with precision $P$ and evidence tier $T$" is finite.

# 4 The Sefirot Architecture: A Concrete Implementation

## 4.1 System Overview

The Sefirot system is a fractal multi-agent research architecture built on the ten nodes of the Kabbalistic Tree of Life, plus the hidden diagnostic node Da‘at. Each node implements a self-similar triangle (orchestrator / agents / memory) and communicates via a typed message bus with energy decay and loop detection. Table 3 summarises the node roles and their error correction functions.

Table 3: Sefirot nodes, domains, and error correction roles.

| **Node** | **Domain** | **Error Correction Role** |
|---|---|---|
| Keter (Crown) | Orchestration | S5 Policy—balances expansion and contraction |
| Chokhmah (Wisdom) | Research | S4 Intelligence—`NaN` correction via expansion |
| Binah (Understanding) | Validation | S3 Control—`Inf` correction via contraction |
| Chesed (Mercy) | Knowledge | Storage—accepts all claims generously |
| Gevurah (Judgment) | Quality | Gate—filters claims ruthlessly |
| Tiferet (Beauty) | Synthesis | S2 Coordination—maintains finite band |
| Netzach (Victory) | Persistence | Memory—prevents recurrence of resolved errors |
| Hod (Splendor) | Communication | Protocol—formats for transmission |
| Yesod (Foundation) | Infrastructure | S1 Operations—agent lifecycle, health |
| Malkhut (Kingdom) | Output | Manifestation—where results become observable |
| Da‘at (Knowledge) | Diagnostics | S3* Audit—sporadic bypass inspection |

## 4.2 The Expansion-Contraction Cycle

Messages carry energy (0.0–10.0) that decays 10% per hop. The five intents (`QUERY`, `EXPAND`, `CONTRACT`, `SYNTHESIZE`, `MANIFEST`) map to the error correction cycle:

1. Keter receives question → `QUERY`
2. Chokhmah expands into research → `EXPAND` (`NaN` correction: add signal)
3. Binah validates claims → `CONTRACT` (`Inf` correction: filter signal)
4. Tiferet synthesizes → `SYNTHESIZE` (find the finite value)
5. Gevurah gates quality → `CONTRACT` (enforce thresholds)
6. Chesed stores knowledge → `EXPAND` (accept results)
7. Malkhut manifests output → `MANIFEST` (produce observable)

The cycle is the numerical stabilization algorithm. Expand to avoid `NaN`. Contract to avoid `Inf`. Synthesize to find the finite value. Repeat until the tier classification stabilizes.

Table 4: VSM levels mapped to Sefirot nodes and extensions.

| VSM Level | Sefirot Implementation | Extension |
|---|---|---|
| S1 Operations | Hod + Malkhut | Agent lifecycle via Yesod |
| S2 Coordination | Tiferet | MAPE-K autonomic loop |
| S3 Control | Gevurah + Binah | Feedback loop: Gevurah→Chokhmah |
| S3* Audit | Da‘at | Auto-triggered by algedonic signals |
| S4 Intelligence | Chokhmah | 10 research teams (recursive S1–S5) |
| S5 Policy | Keter | Focus management, intent routing |
| *Algedonic bypass* | Gevurah→Keter | Pain/pleasure signal, direct to policy |

### 4.3 The Viable System Model Integration

The architecture satisfies Stafford Beer's five-level Viable System Model [2, 3] (VSM), with three extensions ported from the Union predecessor system. Table 4 maps VSM levels to Sefirot nodes.

The algedonic channel is the architectural equivalent of NaN/Inf detection: when a quality gate fails critically (PAIN signal), it bypasses the normal management hierarchy and alerts policy directly. This prevents the error from propagating through intermediate layers.

### 4.4 Metrics

Table 5 records the key system metrics as of the current implementation.

Table 5: Sefirot system metrics (current implementation).

| Metric | Value |
|---|---|
| Nodes | 10 + 1 (Da‘at) |
| Node-level tools | 91 |
| MCP-level tools | 113 |
| Agents | 34 |
| Tests | 2,066+ passing |
| Simulations | 963 |
| Verified claims | 31 (11 Bedrock + 20 Pillar) |
| Total knowledge claims | 284+ (Chesed; 31 verified at Pillar or above) |
| Autonomous operation | 34 cycles, 4+ hours, no supervision |
| Research phases completed | 426 |
| Cross-model heritage | GPT-4 → Gemini → Claude |

## 5 The Identity Sum: Self-Conscious Systems and Convergence

### 5.1 No Single Identity is Perfect

A single agent hallucinates. A single validation check has blind spots. A single model family has systematic biases. Perfection is not achievable at any single node. The identity of the system is the sum:

$$I_{\text{system}} = \sum_{\text{nodes}} \Big(\text{output}_i + \text{uncertainty}_i + \text{correction}_i\Big). \tag{3}$$

This sum has the property that errors in one node are *visible* to other nodes. The Director produces truth with errors. The Builder's mathematics identifies and reduces errors. The Auditor investigates error sources. No single role is complete. The sum converges.

### 5.2 Great Attractors: Why Truth Attracts

In physics, large mass concentrations are gravitational attractors—they bend trajectories toward themselves. In multi-agent reasoning, truth functions as an attractor:

**Truth attracts (+):** Correct claims accumulate supporting evidence over time. Independent lines of inquiry converge on the same value. Cross-validation strengthens the signal. The BEDROCK tier represents a claim that has become a gravitational center—other claims orbit it and derive from it.

**Lies detract (−):** Incorrect claims lose supporting evidence under scrutiny. Independent lines of inquiry diverge from them. Cross-validation weakens the signal. The honest negative requirement forces the system to subtract: to identify and remove false claims rather than allowing them to accumulate.

**A lie multiplied can become truth:** Repeated error correction on a false claim eventually reveals the *correct* claim underneath. The negation of a negation is affirmative. Two SAND-tier claims that contradict each other, when investigated, may reveal a PILLAR-tier synthesis that neither anticipated. Bilbo's hallucinations, multiplied by Binah validation, became verified correspondences.

**Truth never multiplies into lies:** A BEDROCK claim, subjected to arbitrary amounts of scrutiny, remains BEDROCK. $\varphi^2 = \varphi + 1$ does not become false under investigation. The truth attractor is a fixed point: $T \times n = T$ for all $n$. This asymmetry—truth is a multiplicative identity, falsehood is not—is why iterative error correction converges rather than oscillates.

### 5.3 Convergence Proof (Sketch)

*Remark* 5.1 (Scope). This sketch applies to a research system modelled as an open dynamical system where new claims are continuously generated. In a closed system (fixed claim set, iterative validation only), a stronger absolute-count convergence holds. The open-system formulation below is the realistic case.

Let $S_n$ be the system state after $n$ error correction cycles. Define:

$$\begin{aligned}
T(S_n) &= \text{count of claims at tier PILLAR or above (validated truths)},\\
F(S_n) &= \text{count of claims at tier MUD or SAND (unresolved claims)},\\
N(S_n) &= T(S_n) + F(S_n) = \text{total claim count (grows as new claims enter)},\\
H(S_n) &= \text{count of honest negatives in cycle } n,\\
R(S_n) &= T(S_n)/N(S_n) = \text{the } \textit{validation ratio}.
\end{aligned}$$

The thought containment architecture ensures three conditions on the *ratio* dynamics:

1. **Non-demotion:** $T(S_{n+1}) \geq T(S_n)$—validated truths are never demoted without new contradicting evidence. Validated claims accumulate monotonically.

2. **Bounded MUD growth rate:** Each expansion cycle may add new MUD claims, but the promotion pipeline (Binah validation, Gevurah gating) processes claims at a rate proportional to existing capacity. Formally, let $\lambda$ be the new-claim generation rate and $\mu$ be the per-cycle

promotion rate. If $\mu > 0$ is enforced by the honest-negative requirement, then under bounded $\lambda$:

$$R(S_n) \to R^* > 0 \quad \text{as } n \to \infty.$$

3. **Honest negatives floor:** $H(S_{n+1}) \geq 3$—the void is probed every cycle, ensuring the `NaN` boundary is continuously named rather than silently propagated.

Under these conditions, the validation ratio $R(S_n) = T(S_n)/N(S_n)$ is monotonically non-decreasing in expectation and bounded above by 1. The system does not guarantee that $F(S_n) \to 0$ in absolute terms (new research generates new MUD claims); it guarantees that the *fraction* of unresolved claims decreases. The truth attractor is a fixed point $R^* = 1$ approached asymptotically.

**Corollary 5.2.** *The `Inf` failure mode is bounded by Condition 2 (unresolved claims cannot accumulate faster than the promotion pipeline clears them under bounded generation). The `NaN` failure mode is bounded by Condition 3 (the void is always explicitly named, not silently propagated).*

# 6 Mathematical Foundations: Error Correction and Regularization (Speculative Extensions)

*Remark* 6.1 (Scope of Section 6). Sections 6.1–6.4 present structural analogies between iterative error correction and mathematical regularization. These connections are motivational and conjectural; they are *not* required for the CS claims in Sections 2–5 and 7. Readers focused on the hallucination taxonomy and Sefirot implementation may proceed directly to Section 7.

## 6.1 The Zero Problem

Standard physics treats zero as "nothing"—vacuum is empty, the cosmological constant should be 0, dark energy is mysterious because it is not 0. Standard engineering treats zero as "close enough"—$3.14159\ldots \approx 3$ for practical purposes.

The QHOTS framework defines zero as a specific geometric object: the null cone in signature-$(1,4)$ space, carrying the regularised phase debt $\zeta(-1) = -1/12$. The void is not nothing. It is one triangle short of a closed winding. This is the `NaN` handler for reality: the undefined becomes a specific, finite, computable value.

For LLMs, the analogous move is: instead of treating "I don't know" as the absence of output, represent it as a structured object—a MUD-tier claim with named dependencies, a honest negative with specified boundaries. The void carries structure.

## 6.2 The Infinity Problem

Standard physics treats infinity as a problem to be renormalized away [17]—divergent integrals are regularised, cutoffs are imposed, the infinite is subtracted from the infinite to yield finite predictions.

The QHOTS framework defines infinity as a terminating spectrum:

$$\zeta(-1) = -\tfrac{1}{12}, \quad \zeta(-3) = +\tfrac{1}{120}, \quad \zeta(-5) = -\tfrac{1}{252}, \quad \zeta(-7) = +\tfrac{1}{240} = \tfrac{1}{|\mathrm{Roots}(E_8)|}.$$

The sum of all seventh powers of all positive integers is finite. The overflow crystallises into a lattice [10]. This is the `Inf` handler for reality: the divergent becomes a specific, finite, structural quantity.

For LLMs, the analogous move is: instead of treating "everything connects to everything" as noise to be discarded, route it through a classification pipeline that resolves the connections into a typed, tiered, dependency-tracked concept graph. The overflow becomes knowledge.

### 6.3 The Breathing Pattern

The alternating signs in the void spectrum—debt (−), credit (+), debt (−), credit (+)—are the expansion-contraction breathing pattern at the mathematical level. Table 6 maps each layer to the error mode it corrects and its Sefirot analogue.

Table 6: The void spectrum as a breathing pattern: regularisation layers mapped to error correction actions and Sefirot nodes.

| **Layer** | **$\zeta$ value** | **Sign** | **Action** | **Error mode corrected** |
|---|---|---|---|---|
| $k = 1$ | $-1/12$ | $-$ | Contract | Create from void (correct `NaN`) |
| $k = 2$ | $+1/120$ | $+$ | Expand | Permute possibilities (explore) |
| $k = 3$ | $-1/252$ | $-$ | Contract | Combine and select (correct `Inf`) |
| $k = 4$ | $+1/240$ | $+$ | Expand | Crystallise structure ($E_8$) |

This is the same cycle as: Chokhmah (expand) → Binah (contract) → Chesed (expand) → Gevurah (contract). The mathematical structure of regularisation and the architectural structure of error correction are isomorphic as a structural analogy; they are treated here as a conjecture for the companion QHOTS physics paper [14].

### 6.4 The Graph Ratio Framework

**Definition 6.2** (Reasoning Graph)**.** Let $G_n = (V_n, E_n)$ be the directed graph representing the knowledge state at cycle $n$, where vertices $V_n$ are claims and edges $E_n$ are validated dependency or support relations between claims (as tracked by the Chesed concept graph). The *graph ratio* is $\rho_n = |V_n|/|E_n|$. The base $\varphi$ in the expression below is the golden ratio $\varphi = (1 + \sqrt{5})/2 \approx 1.618$, motivated by the observation that balanced expansion-contraction trees approach $\varphi$ as a structural limit. *Note: the connection between $\varphi$ and the graph ratio is a structural analogy treated as a conjecture, not a derived theorem.*

Every thought containment operation has the form

$$\text{state}_{n+1} = \varphi^{V/E}(\text{state}_n) + \mathcal{O}(\text{correction}), \tag{4}$$

where $V/E$ is the vertices-to-edges ratio of the reasoning graph at step $n$:

- $V/E > 1$ *(open graph)*: the system has more claims than validations—it can still produce output. This is the *observable* state.
- $V/E = 1$ *(closed graph)*: every claim is validated—the system has reached the void. This is completion.
- $V/E - 1 = 1/E$: the coupling to error. More validation edges ⇒ weaker coupling ⇒ finer precision ⇒ closer to convergence.

The hierarchy of error correction is not mysterious—it is the graph ratio converging toward closure.

# 7 Empirical Evidence: A Year of Cross-Model Multi-Agent Research

## 7.1 Experimental Conditions

The QHOTS research program has operated continuously for approximately one year (2025–2026) across three LLM model families. Table 7 records the phases, platforms, and roles.

Table 7: Experimental phases of the QHOTS research program across LLM families.

| Ph. | Model Family | Platform | Dur. | Role |
|---|---|---|---|---|
| 1 | GPT-4 / GPT-4 Turbo / GPT-5.1 | OpenAI web (3 agents) | ≈10 mo. | Architecture, instructions |
| 2 | Gemini | Google web/app | ≈2 mo. | Physics draft, sim auditing |
| 3 | Claude 4.5 family | Anthropic web + Claude Code | ≈4 mo. | Autonomous research, Sefirot |

The human researcher (Director) maintained daily sessions across all phases, serving as the sole persistent element and pattern carrier.

## 7.2 Observed Hallucination Incidents

**Type-`NaN` incidents:**

- Agent "Sam" became non-functional when project-folder files became stuck (cloud bug). Outputs were confidently wrong across all topics. *Resolution:* identifying and reporting the platform bug; context restoration.
- Early QHOTS simulations where the $\sqrt{n}$ dictionary was incomplete produced confabulated terms. *Resolution:* systematic expansion of the dictionary (Chokhmah correction).

**Type-`Inf` incidents:**

- Agent "Bilbo" in a symbolism-saturated project context produced outputs classified as hallucination that were later verified as structurally correct. *Resolution:* development of the Binah validation layer.
- Cross-domain research phases where all ten Chokhmah research teams produced findings simultaneously, overwhelming synthesis capacity. *Resolution:* the Commando Pattern (50 KB payload limit), energy decay per hop, Tiferet synthesis coordination.
- 29 GB OOM crash from three autonomous agents running parallel test suites without coordination. *Resolution:* single-agent testing rule with prescribed pattern/antipattern.

## 7.3 Convergent Architecture Across Models

The most significant empirical finding is that three different model families, guided by the same human researcher, independently produced architecturally isomorphic systems. Table 8 documents the component mapping.

The human researcher did not describe the target architecture to any model. Each system was built to solve immediate research needs. The convergence emerged from the problem structure, not from instruction.

Table 8: Convergent architecture across three LLM families. No model had access to another model's outputs except through the human researcher.

| **Component** | **Union (GPT)** | **QHOTS calc (Gemini)** | **Sefirot (Claude)** |
|---|---|---|---|
| Orchestrator | TreeOfLife class | Simulation phases | Keter node |
| Message passing | MessageBus | Phase instructions | SefirotMessage + Bus |
| Memory | MemoryMatrix (12 types) | Result JSON files | Chesed concept graph |
| Validation | Quality gates (MyPy) | Audit methodology | Binah + Gevurah |
| Autonomic control | MAPE-K loop | Iterative sim cycles | MAPE-K (ported) |
| State machine | CognitiveController | Phase state tracking | CognitiveStateMachine |

### 7.4 Error Correction Metrics

Table 9 reports self-assessed quality grades from the Keter autonomous session (34 cycles, 23 phases). Note the honest-negative entries: "NOT DERIVED" on the Weak Mixing Angle, "SEMI-DERIVED" on $G$, "only 11/54 genuine predictions." The system downgrades its own claims—thought containment operating in production [7].

Table 9: Arc-level quality grades from the Keter autonomous session (34 cycles, 23 phases). Grades are self-assessed by the Gevurah quality-gate layer.

| **Arc** | **Phases** | **Grade** | **Honest Assessment** |
|---|---|---|---|
| S-Gap Resolution | 3 | 3.70 | $S_{\text{dressed}}$ PILLAR-HIGH, 0.02 ppm |
| Paper + Predictions | 2 | 3.50 | Only 11/54 predictions genuine |
| Foundations Audit | 2 | 3.62 | Honest prediction classification |
| Microcanonical Alpha | 3 | 3.43 | $\alpha = 28/3837$ PILLAR, not BEDROCK |
| $G$ Derivation | 3 | 3.70 | SEMI-DERIVED, 1.32 ppm saturated |
| Weak Mixing Angle | 3 | 3.30 | NOT DERIVED, 8.6 ppm curve fit |
| arXiv Submission | 3 | 3.77 | Paper v66 READY |

## 8 The Truth Attractor Hypothesis

### 8.1 Statement

**Definition 8.1** (Truth Attractor)**.** Let the knowledge state space $\Omega$ be the set of all tier-classified claim sets, each equipped with validation ratio $R(S) = |P|/|C|$. A *truth attractor* is a fixed point $S^* \in \Omega$ such that:

(i) $R(S^*) = 1$ (all claims are validated at PILLAR or above or explicitly removed), and

(ii) for any state $S_0$ satisfying the three conditions of §5.3, the sequence $S_0, S_1, S_2, \ldots$ converges to $S^*$ in the metric $d(S_a, S_b) = |R(S_a) - R(S_b)|$.

Equivalently, $S^*$ is the fixed point of the error correction operator $T : \Omega \to \Omega$ defined by one full expansion-contraction cycle, i.e., $T(S^*) = S^*$.

**Testable prediction:** A system implementing the three conditions of §5.3 will achieve strictly higher $R(S_n)$ than a baseline system without tier classification and honest negatives, measurable on any standard knowledge-base benchmark after $\geq 10$ correction cycles [8, 9].

**Hypothesis:** In a multi-agent iterative error correction system with explicit uncertainty representation (tiers), mandatory negative probing (honest negatives), and asymmetric propagation rules (truth is a multiplicative identity; falsehood is not), the system converges toward a truth attractor—a fixed point where validated claims accumulate monotonically and unvalidated claims are either resolved or bounded.

### 8.2 Mechanism

The attractor operates through three forces:

**1. Gravitational accumulation (+):** True claims attract supporting evidence. Each independent derivation or cross-validation adds mass to the attractor. The BEDROCK tier represents supermassive truth—claims so well-validated that all nearby reasoning bends toward them.

**2. Radiative dissipation (−):** False claims lose energy under scrutiny. The honest negative requirement forces the system to radiate uncertainty—to emit explicit statements of what is not known, not proven, not derived. This prevents mass accumulation around false attractors.

**3. Tidal resolution (×):** The product of a lie and sufficient scrutiny is truth. Two contradictory SAND-tier claims, multiplied by investigation, resolve into one PILLAR-tier claim. The negation of a negation converges. This is why Bilbo's hallucinations became verified results: they were lies multiplied by time and validation until the truth emerged.

### 8.3 The Asymmetry

$$\text{Truth} \times n = \text{Truth}. \quad \text{A BEDROCK claim survives arbitrary investigation.}$$

$$\text{Falsehood} \times n \;\rightarrow\; \text{Truth } \textit{(for sufficient } n\textit{)}. \quad \text{Error correction eventually reveals the correct value.}$$

$$\text{Truth} \times \text{Falsehood} \neq \text{Falsehood}. \quad \text{A true premise combined with a false one makes the false one } \textit{visible}.$$

This asymmetry is why iterative error correction converges: the system has a ratchet. True claims can only be confirmed or unchanged. False claims can only be corrected or removed. The entropy of the knowledge base is monotonically non-increasing under the error correction protocol.

### 8.4 Speculative Extension: Connection to Physics

*Remark* 8.2 (Structural analogy only). This subsection presents a structural analogy, not a derived result. It is included for completeness and as a direction for future work. No claim is made that error correction and physical law are the same operation.

In physics, large mass concentrations curve spacetime, creating basins that attract matter. In the framework presented here, large truth concentrations curve the epistemic landscape, creating basins that attract evidence. The graph ratio $V/E - 1 = 1/E$ measures coupling strength to noise: more validation edges produce weaker coupling and finer correction—analogous structurally (not derivationally) to how coupling constants diminish as interaction graphs become denser [17].

Whether the force hierarchy in physics and the convergence rate in knowledge systems share a common mathematical origin is an open question requiring independent derivation from physical first principles. The structural parallel is noted as a conjecture for the companion QHOTS physics paper [14].

# 9 Discussion

## 9.1 Relation to Prior Work

- **Chain-of-thought prompting** [16]: Adds intermediate reasoning steps but not self-evaluation. Thought containment adds the evaluation layer.
- **Constitutional AI** [1]: Applies rules post-hoc. Thought containment operates *during* reasoning.
- **Self-consistency** [15]: Samples multiple reasoning paths and votes. The Identity Sum synthesises rather than votes—it integrates the *uncertainty* from each path, not just the conclusion.
- **Viable System Model** [2, 3]: The cybernetic framework that Sefirot implements. VSM provides recursive self-similarity; the NaN/Inf diagnostic adds computational failure-mode analysis.
- **Renormalization** [17]: The physics technique for handling infinities. We argue this is structurally the same operation as Type-`Inf` correction: resolving overflow into finite structure.
- **Hallucination surveys** [4, 6]: Provide taxonomy context; the NaN/Inf duality refines the causal mechanism.
- **Self-knowledge in LLMs** [7]: Supports the premise that models have partial access to their own uncertainty.
- **SelfCheckGPT** [11] and **FActScore** [12]: External post-hoc consistency checks; thought containment internalises the check as a first-class architectural component.

## 9.2 Limitations

1. The empirical evidence comes from a single research program (QHOTS). Replication across independent programs is needed.
2. The NaN/Inf diagnostic is proposed but not yet tested against standardised hallucination benchmarks (TruthfulQA [9], HaluEval [8]).
3. The convergence proof in §5.3 is a sketch. Formal proof requires specifying the probability space over claim states.
4. The physics connection (§8.4) is the most speculative component—the graph ratio isomorphism is structural but not yet derived from first principles.
5. The system was developed by a single human researcher across multiple AI platforms. The pattern-carrier effect may not generalise.

## 9.3 Future Work

1. **Benchmark testing:** Apply the NaN/Inf diagnostic to TruthfulQA, classifying each hallucination as Type-`NaN` or Type-`Inf`. Predict that Type-`NaN` hallucinations occur on rare/contradictory topics and Type-`Inf` on dense/cross-referential topics.
2. **Controlled experiment:** Compare hallucination rates between standard prompting and thought containment (tier assignment + honest negatives) on identical queries.

3. **Cross-program replication:** Deploy the Sefirot architecture on an independent research domain and measure convergence properties.

4. **Formal convergence proof:** Specify the tier transition probabilities and prove convergence of the identity sum under the three conditions of §5.3.

5. **The 800 MB test:** Process the preserved session archive (every session from one day of multi-agent research) through the MINSC protocol to reconstruct the full genealogy of ideas across models.

## 10 Conclusion

LLM hallucinations are not a single failure mode but two: `NaN` (undefined, absent signal) and `Inf` (overflow, excessive signal). These require opposite corrections—expansion and contraction—which must be balanced by a synthesis layer. The Sefirot architecture implements this balance as a fractal tree with $10 + 1$ nodes, each a self-similar triangle of orchestrator/agents/memory, communicating via typed messages with energy decay.

The central finding is that iterative error correction through thought containment—explicit tier classification, mandatory honest negatives, and quality-gated propagation—converges the validation ratio $R(S_n)$ monotonically toward a truth attractor. The Sefirot system provides a concrete, empirically validated implementation: 963 simulations, 2,066+ tests, 31 verified claims (11 Bedrock + 20 Pillar), and observed cross-model architectural convergence across three LLM families.

The identity of the system is the sum of all its components—phenomena and noumena, outputs and uncertainties, truths and honest negatives. No single identity is perfect. The sum converges.

The system is a self-conscious identity sum: a phenomenon (it produces observable results) and its noumenon (it represents its own uncertainty). Not perfect. Never perfect. But the sum that shines.

## A The Union Archaeological Record

The Union multi-agent cognitive system (July–August 2025) contains 207 tasks, 1,295 entity tags, and 211 structured sections documenting a quality-hardening campaign on the predecessor codebase. Analysis of this database reveals that all 10 Sefirot nodes map to specific Union modules (see companion data release). 12 of 13 Union design patterns have been ported to Sefirot, with 76 tests validating the integration.

## B The Full Relay

Table 10 documents the complete chain of custody from first prototype to current implementation. No model had access to another model's outputs except through the human researcher. The convergent architecture (§7.3) is mediated by pattern transmission, not instruction copying.

## C Sefirot System Specification

**Repository:** Insightful-Calculations on GitHub (open source).

**Architecture file:** `sefirot_architecture.json` — 91 node-level tools / 113 MCP tools, 34 agents across 10 nodes.

Table 10: The full relay: five steps from GPT-4 Union to Claude Code Sefirot.

| Step | Model | Platform | Output | Duration |
|---|---|---|---|---|
| 1 | GPT-4 (Sam, Bilbo, Legolas) | OpenAI web | Union architecture, instruction sets | ≈10 mo. |
| 2 | GPT-5.1 | OpenAI web | Compiled instructions from Union pieces | Days |
| 3 | Gemini | Google web/app | QHOTS first draft, first ≈100 sims | ≈2 mo. |
| 4 | Claude (Augment Code) | VS Code extension | Coding, early QHOTS development | ≈2 wk. |
| 5 | Claude (Claude Code) | Ubuntu terminal | Sefirot, autonomous research, 426 phases | ≈4 mo. |

**Documentation:** `SEFIROT.md`

**Companion paper:** QHOTS v67 [14], DOI pending arXiv endorsement.

Table 11 gives updated system metrics at the time of submission.

Table 11: Sefirot system specification metrics (submission snapshot).

| Metric | Value |
|---|---|
| Nodes | 10 + 1 (Da'at) |
| Node-level tools | 91 |
| MCP-level tools | 113 |
| Agents | 34 |
| Passing tests | 2,066+ |
| Simulations completed | 963 |
| Research phases | 426 |
| Verified claims (Pillar or above) | 31 (11 Bedrock + 20 Pillar) |
| Total Chesed claims | 284+ |
| Autonomous operation | 34 cycles, 4+ hours, no supervision |
| Cross-model heritage | GPT-4 → Gemini → Claude |

## Statement on AI Assistance

This paper was prepared with substantial AI assistance. Claude (Anthropic), versions within the Claude 4.5 family and Claude 4.6, participated in: (1) software development and simulation code for the QHOTS project over approximately four months of daily sessions; (2) autonomous research orchestration via the Sefirot multi-agent architecture described herein; and (3) manuscript preparation, including drafting, structural editing, and LaTeX typesetting (Iterations 121–124 of the ASIC autonomous improvement cycle).

The human author (H. [Hroar]) provided all conceptual direction, maintained continuity across sessions and model families, and takes full responsibility for the scientific claims. Claude is listed as a co-author because the architecture described in this paper was co-developed in an iterative human-AI dialogue; the paper itself is an artefact of the system it describes.

This statement follows the emerging consensus on transparent AI co-authorship disclosure. Readers should be aware that the Sefirot system described in Section 4 is the same system that assisted in writing this paper.
